Description

[0001] This invention relates to an electrosurgical instrument for the treatment of tissue in the presence of an electrically-conductive fluid and to electrosurgical apparatus including such an instrument.

[0002] Endoscopic electrosurgery is useful for treating tissue in cavities of the body, and is normally performed in the presence of a distension medium. When the distension medium is a liquid, the technique is commonly referred to as underwater electrosurgery, this term denoting electrosurgery in which living tissue is treated using an electrosurgical instrument with a treatment electrode or electrodes immersed in liquid at the operation site. A gaseous medium is commonly employed when endoscopic surgery is performed in a distensible body cavity of larger potential volume in which a liquid medium would be unsuitable, as is often the case in laparoscopic or gastroenterological surgery.

[0003] Underwater surgery is commonly performed using endoscopic techniques, in which the endoscope itself may provide a conduit (commonly referred to as a working channel) for the passage of an electrode. Alternatively, the endoscope may be specifically adapted (as in a resectoscope) to include means for mounting an electrode, or the electrode may be introduced into a body cavity via a separate access means at an angle with respect to the endoscope - a technique commonly referred to as triangulation. These variations in technique can be subdivided by surgical speciality, where one or other of the techniques has particular advantages given the access route to the specific body cavity. Endoscopes with integral working channels, or those characterised as resectoscopes, are generally employed when the body cavity may be accessed through a natural opening - such as the cervical canal to access the endometrial cavity of the uterus, or the urethra to access the prostate gland and the bladder. Endoscopes specifically designed for use in the endometrial cavity are referred to as hysteroscopes, and those designed for use in the urinary tract include cystoscopes, urethrosopes and resectoscopes. The procedures of transurethral resection or vaporisation of the prostate gland are known as TURP and EVAP respectively. When there is no natural body opening through which an endoscope may be passed, the technique of triangulation is commonly employed. Triangulation is commonly used during underwater endoscopic surgery on joint cavities such as the knee and the shoulder. The endoscope used in these procedures is commonly referred to as an arthroscope.

[0004] Electrosurgery is usually carried out using either a monopolar instrument or a bipolar instrument. With monopolar electrosurgery, an active electrode is used in the operating region, and a conductive return plate is secured to the patient's skin in a position remote from the operating site. With this arrangement, current passes from the active electrode through the patient's tissues to the external return plate. Since the patient rep-

resents a significant portion of the circuit, input power levels have to be high (typically 150 to 250 watts), to compensate for the resistive current limiting of the patient's tissues and, in the case of underwater electrosurgery, power losses due to the fluid medium which is rendered partially conductive by the presence of blood or other body fluids. Using high power with a monopolar arrangement is also hazardous, due to the tissue heating that occurs at the return plate, which can cause severe skin burns. There is also the risk of capacitive coupling between the instrument and patient tissues at the entry point into the body cavity.

[0005] When performing surgery in body cavities, vital structures often lie in close proximity to the site of application, and these structures may be damaged by the collateral spread of the electrosurgical effect. Also of concern when using monopolar electrosurgery is that the operating voltage is elevated to overcome the resistive current limiting of the patient's tissues or to overcome carbonisation of the application electrode. Arcing by direct coupling to adjacent structures, or through breaches in insulation, may produce accidental tissue damage outside the narrow field of view of the endoscope. There is also the risk of capacitive coupling between the instrument and the patient's tissues at the entry point into the body cavity such that an electrosurgical energy may be coupled to tissue at the entry point. This coupled energy can sometimes be sufficient to cause burning. These risks of using monopolar electrosurgery during endoscopic procedures are now well recognised, and have driven a move towards adoption of bipolar surgery.

[0006] With bipolar electrosurgery, a pair of electrodes (an active electrode and a return electrode) are used together at the tissue application site. This arrangement has advantages from the safety standpoint, due to the relative proximity of the two electrodes so that radio frequency currents are limited to the region between the electrodes. However, the depth of effect is directly related to the distance between the two electrodes; and, in applications requiring very small electrodes, the inter-electrode spacing becomes very small, thereby limiting tissue effect and the output power. Spacing the electrodes further apart would often obscure vision of the application site, and would require a modification in surgical technique to ensure correct contact of both electrodes with the tissue.

[0007] There are a number of variations to the basic design of the bipolar probe. For example, U.S. Patent Specification No. 4706667 describes one of the fundamentals of the design, namely that the ratio of the contact areas of the return electrode and of the active electrode is greater than 7:1 and smaller than 20:1 for cutting purposes. This range relates only to cutting electrode configurations. When a bipolar instrument is used for desiccation or coagulation, the ratio of the contact areas of the two electrodes may be reduced to approximately 1:1 to avoid differential electrical stresses occurring at

the contact between the tissue and the electrodes.

[0008] The electrical junction between the return electrode and the tissue can be supported by wetting of the tissue by a conductive solution such as normal saline. Both monopolar and bipolar probe arrangements often provide a means of suction and irrigation, primarily intended to wash the operative site. In such a case, the active electrode is retracted within the irrigation sheath to enable direct contact of the sheath with the tissue without the risk of mechanical damage to the tissue by the exposed electrode. No surgical effect can be produced with the electrode retracted, or during the passage of saline. As a secondary benefit, this arrangement allows the wetting of tissue to reduce contact impedance.

[0009] In bipolar needle arrangements, one of the obvious limitations is that the active electrode must be completely buried in the tissue to enable the return electrode to complete the circuit. Another problem is one of orientation: even a relatively small change in application angle from the ideal perpendicular contact with respect to the tissue surface, will change the electrode contact area ratio, so that a surgical effect can occur in the tissue contacting the return electrode.

[0010] The applicants have developed a bipolar instrument suitable for underwater electrosurgery using a conductive liquid or gaseous medium. This electrosurgical instrument for the treatment of tissue in the presence of a fluid medium, comprises an instrument body having a handpiece and an instrument shaft and an electrode assembly, at one end of the shaft. The electrode assembly comprises a tissue treatment electrode which is exposed at the extreme distal end of the instrument, and a return electrode which is electrically insulated from the tissue treatment electrode and has a fluid contact surface spaced proximally from the exposed part of the tissue treatment electrode. In use of the instrument, the tissue treatment electrode is applied to the tissue to be treated whilst the return electrode, being spaced proximally from the exposed part of the tissue treatment electrode, is normally spaced from the tissue and serves to complete an electrosurgical current loop from the tissue treatment electrode through the tissue and the fluid medium. This electrosurgical instrument is described in the specification of the applicants' European Patent Application No. 0771,176, which has the same filing date as the present application and does not form prior art in the sense of Article 54 EPC.

[0011] The electrode structure of this instrument, in combination with a conductive distension medium largely avoids the problems experienced with monopolar or bipolar electrosurgery. In particular, input power levels are much lower than those generally necessary with a monopolar arrangement (typically 100 watts). Moreover, because of the relatively large spacing between its electrodes, an improved depth of effect is obtained compared with conventional bipolar arrangements.

[0012] This type of electrosurgical instrument is de-

signed primarily for use in a saline environment, and so cannot be used in open air or gas-filled operating environments.

[0013] An electrosurgical instrument according to the first part of present claim 1 is disclosed in WO-A-94/10924.

[0014] The aim of the invention is to provide an irrigated bipolar electrosurgical instrument that can be used in open air or gas-filled environments, in body fluids, or by insertion into tissue by the creation of a conductive fluid environment around the tip of the instrument.

[0015] The present invention provides an electrosurgical instrument for the treatment of tissue in the presence of an electrically-conductive fluid, the instrument comprising an instrument shaft and an electrode assembly at one end of the shaft, the electrode assembly comprising a tissue treatment electrode and a return electrode which is electrically insulated from the tissue treatment electrode by means of an insulation member, the tissue treatment electrode being exposed at the extreme distal end of the instrument, and the return electrode having a fluid contact surface spaced from the exposed end of the tissue treatment electrode by the insulation member, wherein the instrument further comprises feed means for feeding electrically-conductive fluid to the region of the exposed end of the tissue treatment electrode in such a manner as to define, in use, a conductive fluid path that completes an electrical circuit between the tissue treatment electrode and the return electrode, and wherein the return electrode is a tubular member which is externally coated in insulation.

[0016] In this way, it is possible to create a local conductive fluid environment around the tip of an electrosurgical instrument by delivering the fluid through the instrument in such a manner that the return electrode can be positioned remote from the tissue treatment electrode on or within the shaft of the instrument.

[0017] The electrode structure of this instrument thus simulates a monopolar configuration, with one active (tissue treatment) electrode and a remote return electrode, the return electrode being positioned on the instrument shaft to provide all the advantages of bipolar electrosurgery without the drawbacks. The separation of the two electrodes is supported by the delivery of the conductive medium, and allows higher powers to be delivered compared to conventional bipolar electrosurgery, but yet at power levels lower than conventional monopolar electrosurgery. The arrangement can also produce a contact vaporisation of tissue comparable to that of laser surgery.

[0018] The return electrode is spaced from the tissue treatment electrode so that, in use, it does not contact the tissue to be treated, and so that the electrical circuit is always completed by the conductive fluid, and not simply by arcing between the electrodes. Indeed, the arrangement is such that arcing between adjacent parts of the electrode assembly is avoided, thereby ensuring

that the tissue treatment electrode can become enveloped in a vapour pocket so that tissue entering the vapour pocket becomes the preferred path for current to flow back to the return electrode via the conductive fluid.

[0019] The electrosurgical instrument of the invention is useful for dissection, resection, vaporisation, desiccation and coagulation of tissue and combinations of these functions with particular application in laparoscopic, colposcopic (including vaginal speculum) and open surgical procedures on the female genital tract and adnexal related diseases. Laparoscopic operative procedures may include: removal of subserosal and pedunculated fibroids, ablation of ectopic endometrium, ovarian cystectomy and ovarian drilling procedures; oophorectomy, salpingo-oophorectomy, subtotal hysterectomy and laparoscopically assisted vaginal hysterectomy (LAVH) as may be performed for benign or malignant diseases; laparoscopic uterosacral nerve ablation (LUNA); fallopian tube surgery as correction of ectopic pregnancy or complications arising from acquired obstructions; division of abdominal adhesions; and haemostasis.

[0020] The electrosurgical instrument of the invention is also useful in the lower female genital tract, including treatment of cervix, vagina and external genitalia whether accessed directly or using instrumentation comprising generally speculae and colposcopes. Such applications include: vaginal hysterectomy and other pelvic procedures utilising vaginal access; LLETZ/LEEP procedure (large loop excision of the transformation zone) or excision of the transformation zone of the endocervix; removal of cystic or septic lesions; ablation of genital or venereal warts; excision of benign and malignant lesions; cosmetic and surgical repairs including vaginal prolapse; excision of diseased tissue; and haemostasis.

[0021] The electrosurgical instrument of the invention is also useful for dissection, resection, vaporisation, desiccation and coagulation of tissue and combinations of these functions with particular application in surgery on the ear nose and throat (ENT) and more particularly procedures performed on the oropharynx, nasopharynx and sinuses. These procedures may be performed through the mouth or nose using speculae or gags or using endoscopic techniques such as functional endoscopic sinus surgery (FESS). Functional endoscopic sinus procedures may include: removal of chronically-diseased, inflamed and hypertrophic mucus linings, polyps and neoplasms from the various anatomical sinuses of the skull; excision of diseased tissue; and haemostasis. Procedures on the nasopharynx may include: removal of chronically-diseased, inflamed and hypertrophic mucus linings, polyps and neoplasms from the turbinates and nasal passages; submucosa resection of the nasal septum; excision of diseased tissue; and haemostasis. Procedures on the oropharynx may include: removal of chronically-diseased, inflamed and hypertrophic tissue, polyps and neoplasms particularly as they occur related to the tonsil, adenoid, epi-glottic and supra-glottic re-

gions, and salivary glands; as an alternative method to perform the procedure commonly known as laser assisted uvulopalatoplasty (LAUP); excision of diseased tissue; and haemostasis.

[0022] It is evident from the scope of applications of the invention that it has further additional applications for dissection, resection, vaporisation, desiccation and coagulation of tissue and combinations of these functions in general laparoscopic, thoracoscopic and neurosurgical procedures, being particularly useful in the removal of diseased tissue and neoplastic disease whether benign or malignant.

[0023] Surgical procedures using the electrosurgical instrument of the invention include introducing the electrode assembly to the surgical site whether through an artificial (cannula) or natural conduit which may be in an anatomical body cavity or space or one created surgically either using the instrument itself or by another technique. The cavity or space may be distended during the procedure using a fluid, or may be naturally held open by anatomical structures. The surgical site may be bathed in a continuous flow of conductive fluid, such as saline solution, to create a locally-irrigated environment around the tip of the electrode assembly in a gas-filled cavity or on an external body surface or other such tissue surfaces exposed during part of a surgical procedure. The irrigating fluid may be aspirated from the surgical site to remove products created by application of the RF energy, tissue debris or blood. The procedures may include simultaneous viewing of the site via an endoscope or using an indirect visualisation means.

[0024] In a preferred embodiment, the instrument further comprises removal means for removing electrically conductive fluid from the region of the exposed end of the tissue treatment electrode. The removal means is particularly important when the conductive fluid is a liquid such as saline, as saline heated up by the electrosurgical output needs to be removed to prevent the risk of collateral tissue damage.

[0025] By continually feeding electrically-conductive fluid such as saline to the region of the tissue treatment (active) electrode, and continually removing the fluid from this region, it is possible to create a local fluid field at the active electrode. Moreover, as fluid is constantly replenished in this region, the temperature of the active electrode can be maintained at a desired level.

[0026] Advantageously, the removal means is constituted by a fluid return channel formed within the instrument shaft, and by means for applying suction to the proximal end of the fluid return channel, and the feed means is constituted by a fluid feed channel formed within the instrument shaft. The fluid feed channel may be positioned around the fluid return channel.

[0027] In a preferred embodiment, the return electrode is a tubular member which is coated with an insulating sheath, the coated return electrode constituting the instrument shaft. Advantageously, the inner surface of the tubular member constitutes the return electrode.

Preferably, the tubular member is made of stainless steel. In this case, the tissue treatment electrode may be supported centrally within the tubular member by an insulating spacer. Conveniently, the insulating spacer is made of a ceramic material, silicone rubber or glass.

[0028] The instrument may further comprise a tube extending proximally of the spacer. Preferably, the feed channel is constituted by the annular space between the return electrode and the tube, and the return channel is constituted by the interior of the tube and aperture means extending through the spacer.

[0029] Alternatively, the instrument may further comprise a second return electrode constituted by a second tubular stainless steel member positioned concentrically within the first-mentioned tubular stainless steel member. In this case, the feed channel may be constituted by the annular space between the two return electrodes, and the return channel is constituted by the annular space between the second return electrode and the tube.

[0030] The invention also provides electrosurgical apparatus comprising a radio frequency generator and an electrosurgical instrument for treatment of tissue in the presence of an electrically-conductive fluid medium, wherein the electrosurgical instrument is as defined above.

[0031] Advantageously, the radio frequency generator includes control means for varying the output power delivered to the electrodes, the control means being such as to provide output power in first and second output ranges, the first output range being for powering the electrosurgical instrument for tissue desiccation, and the second output range being for powering the electrosurgical instrument for tissue removal by cutting or vaporisation. Preferably, the first output range is from about 150 volts to 200 volts, and the second output range is from about 250 volts to 600 volts, the voltages being peak voltages.

[0032] Advantageously, the return electrode is spaced proximally with respect to the tissue treatment electrode, and the electrode assembly is introduced into the selected operation site such that the tissue treatment electrode is positioned at least adjacent to the tissue to be treated, with the vapour pocket in contact with the tissue, and with the return electrode in contact with the electrically conductive fluid, the electrode structure being manipulated to achieve at least vaporisation of the tissue.

[0033] The invention will now be described in greater detail, by way of example, with reference to the drawings, in which:-

Figure 1 is a diagram showing an electrosurgical apparatus constructed in accordance with the invention;

Figure 2 is a schematic longitudinal sectional view of the distal end of a first form of electrosurgical in-

strument for use with the apparatus of Figure 1; and

Figure 3 is a schematic longitudinal sectional view of a second form of electrosurgical instrument for use with the apparatus of Figure 1.

[0034] Each of the electrosurgical instruments described below is intended to be used with a conductive medium such as normal saline or argon. Each instrument has a dual-electrode structure, with the conductive medium acting as a conductor between the tissue being treated and one of the electrodes, hereinafter called the return electrode. The other electrode is applied directly, or immediately adjacent, to the tissue, and is hereinafter called the tissue treatment (active) electrode. In many cases, use of a liquid medium is preferable, as it prevents excessive electrode temperature in most circumstances, and largely eliminates tissue sticking.

[0035] Referring to the drawings, Figure 1 shows electrosurgical apparatus including a generator 1 having an output socket 2 providing a radio frequency (RF) output for an instrument in the form of a handpiece 3 via a connection cord 4. Activation of the generator 1 may be performed from the handpiece 3 via a control connection in the cord 4, or by means of a footswitch unit 5, as shown, connected separately to the rear of the generator 1 by a footswitch connection cord 6. In the illustrated embodiment, the footswitch unit 5 has two footswitches 5a and 5b for selecting a desiccation mode and a vaporisation mode of the generator 1 respectively. The generator front panel has push buttons 7a and 7b for respectively setting desiccation and vaporisation power levels, which are indicated in a display 8. Push buttons 9a are provided as an alternative means for selection between the desiccation and vaporisation modes.

[0036] The handpiece 3 mounts a detachable electrosurgical instrument E, such as the electrode units E1 and E2 to be described below.

[0037] Figure 2 shows the distal end of the first form of the electrosurgical instrument E1. The instrument E1 is formed with an electrode assembly at the distal end thereof, the electrode assembly comprising a central tissue treatment (active) electrode 11 and a tubular return electrode 12. The active electrode 11 is made of twisted noble metal (such as platinum/iridium or platinum/tungsten), and the return electrode is a stainless steel tube. The return electrode 12 is completely enveloped by a polyimide insulating sheath 13. The return electrode 12 extends the entire length of the electrosurgical instrument E1, and constitutes the shaft of the instrument.

[0038] The electrodes 11 and 12 are provided with current from the radio frequency (RF) generator 1 (not shown in Figure 2), the return electrode 12 being directly connected to the generator and the active electrode 11 being connected via a copper conductor 14. The generator 1 may be as described in the specification of our European Patent Application No.0754437. The active electrode 11 is held centrally within the return electrode

12 by means of a ceramic insulator/spacer 15. The insulator/spacer 15 has a generally cylindrical portion 15a surrounding the junction between the active electrode 11 and the conductor 14 and the adjacent regions of these two members, and four radially-extending, equispaced wings 15b which contact the internal circumferential wall of the return electrode 12 to hold the insulator/spacer, and hence the active electrode 11, centrally within the return electrode.

[0039] A tube 16, made of an insulating material such as PTFE, is a friction fit around the proximal end of the cylindrical portion 15a of the insulator/spacer 15, and extends substantially along the entire length of the instrument. The tube 16 defines, together with the return electrode 12, a coaxial saline supply channel 17, the interior of the tube 16 defining a saline return channel 18. In use, saline is fed to the channel 17 under gravity (no pumping being required), and saline is removed via the channel 18 and apertures (not shown) in the cylindrical portion 15a of the insulator/spacer 15 by means of suction. Preferably, the suction is carried out by a low noise pump (not shown) such as a moving vane pump or a diaphragm pump, rather than by using a high speed impeller. As the tubing leading to the pump will intermittently contain small quantities of saline, a large vacuum (at least 500 mBar) is required. However, the quantity of gas and liquid to be removed is comparatively small, and this permits the use of a moving vane or diaphragm pump, although a high volume peristaltic pump could also be used.

[0040] To circumvent the requirement for pump sterilisation, the pump operates via a disposable fluid trap (not shown) incorporating a 10µm PTFE filter. This filter prevents both exhausted fluids and gas particulates from being drawn in by the pump and contaminating its workings and the surrounding environment.

[0041] The instrument EI described above is intended for use in open air or gas filled environments, in body fluids, or by insertion into tissue by the creation of a conductive fluid environment around the tip of the instrument; and it is so arranged that it is possible to create a local saline field at a distal end of the instrument. This instrument EI can, therefore, be used for laparoscopic applications. In use, saline is fed to the active electrode 11 via the channel 17, the saline providing a conductive medium to act as a conductive path between the tissue being treated and the return electrode 12. By varying the output of the generator 1, the instrument can be used for tissue removal by vaporisation, for cutting or for desiccation. In each case, as saline contacts the active electrode 11, it heats up until it reaches an equilibrium temperature dependent upon the power output of the generator 1 and the flow rate of the saline. In equilibrium, as fresh saline is fed via the channel 17 to the active electrode 11, the exterior temperature of the shaft is maintained at the same temperature as of that of the surrounding saline. As the insulating sheath 13 completely covers the external surface of the return elec-

trode 12, accidental contact between the return electrode and tissue is avoided.

[0042] One of the advantages of using a low saline flow rate, is that the saline temperature can reach boiling point. However, as there is a continuous flow of saline, there is a temperature gradient rise in the saline from the return electrode 12 to the active electrode 11. This temperature gradient is important, as the hotter saline adjacent to the active electrode 11 reduces the power threshold requirement to reach vaporisation. Although the flow rate requirement can be calculated on the basis of the input power, the flexibility of the generator 1 in maintaining optimum power density means that the flow rate is non-critical. For example, if the generator is set for 100 W, then the maximum flow rate is theoretically calculated as follows:

$$\begin{aligned} \text{Flow rate} &= \text{power/specific heat capacity} \\ &= 100/4.2 \times 75 \text{ cc/s} \\ &= 0.32 \text{ cc/s} \\ &= 19 \text{ cc/min} \end{aligned}$$

[0043] This assumes an initial saline temperature of 25°C, and a heat capacity of 4200 J/kg/°C.

[0044] Although during vaporisation saline is brought into the vapour state, the vapour is only stable around the active electrode 11. Thus, the energy absorbed by virtue of the latent heat of vaporisation can be ignored, as this energy is recovered by freshly-arriving saline.

[0045] Another important factor is that, due to the very short circuit path of the saline, the current may be regarded as flowing along a number of different paths, which, therefore, do not have the same power density. Consequently, vaporisation can occur at flow rates higher than the calculated maximum, due to the unequal power densities within the saline environment. However, the amount of vaporisation occurring along the length of the active electrode 11 will depend upon the flow rate.

[0046] As the saline is heated up by the active electrode 11, it is potentially damaging to tissue as it can cause thermal necrosis. It is important, therefore, that all the heated saline is recovered and exhausted from the patient before coming into contact with the tissue adjacent to the application site. It is for this reason that there is suction from the active electrode 11 to an exhaust reservoir (not shown). However, by ensuring that the suction occurs in excess, no saline can then escape from region of the active electrode 11 other than via the saline return channel 18. Any saline which escapes transversely beyond the exterior shaft falls away from the current path, and so is not heated. The priority is, therefore, to ensure that the hottest saline is removed. As the thermal gradient is at a maximum adjacent to the active electrode 11 this is the most appropriate exhaust point for the saline. It is for this reason that the saline is exhausted through the cylindrical portion 15a of the insulator/spacer 15.

[0047] Another important consideration in deciding

the point of saline evacuation is the potential for blockage of the exhaust path. This could occur when cutting or vaporising tissue in such a way as to free small tissue particles which could easily block the exhaust. The exhaust point is, therefore, selected to be at the highest energy density point on the active electrode 11. This measure ensures that any tissue approaching the exhaust point is instantly vaporised into solution, thereby avoiding the potential for blockage.

[0048] Another significant advantage of ensuring a high degree of suction during tissue removal by vaporisation, is that any smoke which has not been absorbed by the saline is also evacuated. This is important, because smoke is capable of transmitting viable biological particles, and this could lead to infection.

[0049] As mentioned above, the power threshold for vaporisation is not well defined. If the instrument E1 were operating in a static conductive medium, then the vaporisation threshold would be well defined by an impedance switching point where the electrode impedance suddenly rises as a result of vapour pockets forming around the active electrode 11. The threshold is normally dependent upon the dissipation mechanism of the saline. In a static environment, the dissipation mechanism is predominantly by convection currents within the saline. Under these circumstances, the power threshold for vaporisation is defined by the input power into the electrode active region being in excess of the dissipation from the saline. However, in the embodiment, described above, the saline around the active electrode 11 is continually refreshed. If it were not, then the only dissipation mechanism would be by latent heat of vaporisation, and the saline would quickly evaporate. By providing a flow, the threshold power level is increased. However, the threshold power level is dependent on the saline refresh rate at the very periphery of the active electrode 11. The refresh rate at this boundary layer can be modified by altering the surface finish of the active electrode 11. For example, if the active electrode 11 had a smooth surface, then saline would be rapidly refreshed, as a rapid flow rate would be established. However, as the active electrode 11 has an irregular finish, the refresh rate of pockets within the irregular surface is diminished. Thus, the irregular surface traps saline (or at least delays the refresh), and so absorbs more power before being replaced. In other words, the power threshold is decreased by the irregular active electrode surface. This is a highly desirable property, as the electrode power requirement drops substantially without adversely affecting tissue performance. The threshold power is further reduced because the active electrode is constructed so as to provide a capillary action. Thus, even in the vaporised state, the active electrode 11 is intermittently wetted. By ensuring that this wetting wets the entire active electrode 11 by capillary action, there is a continual source of vapour which minimises the intermittent wetting, and so further reduces the power demand.

[0050] To vaporise tissue, it is necessary for the saline

being fed from the channel 17 to be in contact with the tissue, as well as with the active electrode 11. The saline, therefore, has to form a constant drip enveloping the active electrode 11. The tip of the active electrode 11 is, therefore, designed so that the saline and the active electrode simultaneously contact tissue regardless of angle. If the flow of saline from the channel 17 to the active electrode 11 were completely annular, saline could flow from one side to the other, in which case the active electrode could be only partially enveloped. It is to prevent this, that the annular channel 17 is segmented by the wings 15b so as to ensure a saline flow on the uppermost surface. This also improves the adherence of the incoming saline by increasing the capillary action.

[0051] When the tip of the active electrode 11 comes into contact with the tissue, the region touching the tissue suddenly loses its ability to dissipate power via the saline. Whilst the return path is made up of a flow of saline, the tissue has no mechanism for power dissipation and therefore quickly heats up to the point where it is vaporised.

[0052] The effectiveness of the instrument in vaporising tissue is dependent on the ratio between the supported 'drip' and the length of the active electrode 11. A longer active electrode 11 is the most demanding, as the ability to maintain a constant 'drip' is reduced. However, once the active electrode 11 has vaporised a pocket within the tissue, so that the return electrode 12 is closer to the tissue surface, vaporisation becomes easier, as there is a smaller voltage drop across the saline, simply because it forms a smaller part of the electrical circuit.

[0053] By varying the output of the generator 1, the instrument E1 can also be used for desiccation (coagulation). In this case, the generator is controlled so that small vapour bubbles form on the surface of the active electrode 11, but insufficient vapour is produced to provide a vapour bubble (pocket) surrounding the active tip of the electrode 1, the vapour bubble being essential for tissue removal by vaporisation.

[0054] The generator 1 is controlled in such a manner that it has respective output ranges for tissue desiccation and for tissue removal by vaporisation. The former range is from 150 volts to 200 volts, and the latter range is from 250 volts to 600 volts, the voltages being peak voltages. In the vaporisation mode, the generator 1 is controlled in such a manner as to prevent the active electrode 11 overheating. This requires a reduction in the output voltage of the generator 1 once a vapour pocket has been established. The generator 1 and its control means are described in greater detail in the specification of our European Patent Application No. 0754437.

[0055] The coagulation from this electrode is vastly superior to any conventional bipolar electrode. The reasons are two fold. Firstly, the coagulation mechanism is not merely by electrical current in the tissue, but is also due to the heated saline. Secondly, under normal cir-

cumstances, the weakest link in providing electrical power to the tissue is the electrode/tissue interface, as this is the point of highest power density, and so imposes a power limit. If too high a power level is attempted, the tissue at the interface quickly desiccates, far faster than the larger cross-section of tissue forming the remaining circuit. If a lower power is selected, the interface can dissipate the temperature rise by mechanisms other than evaporation. Consequently, the interface remains intact longer, and so a greater depth of effect can be achieved. In this embodiment, the electrical interface is much stronger by virtue of the saline, and it is not possible completely to desiccate the target tissue. Thus, power can be delivered at a higher rate and for a longer period, resulting in a depth of effect which is purely time and power related.

[0056] Figure 3 shows the distal end of the second form of electrosurgical instrument. This instrument is a modification of that shown in Figure 2, so like reference numerals will be used for like parts, and only the modifications will be described in detail. The main modification is that the instrument of Figure 2 includes two coaxial, tubular return electrodes 12 and 12', the return electrode 12' being slightly shorter than the return electrode 12 and being positioned therewithin. The annular gap between the two return electrodes 12 and 12' constitute the saline feed channel 17, and the saline return channel 18 is constituted by the annular gap between the return electrode 12' and the central construction constituted by the cylindrical portion 15a of the insulator/spacer 15 and the tube 16. The tube 16 is also modified to form a friction fit around both the proximal end of the cylindrical portion 15a of the insulator/spacer 15 and the active conductor 14.

[0057] The advantage of the instrument of Figure 3 is that, when it is used to create vaporised pockets in a tissue surface (for example in an embedded tumour) there is less chance of the return path of saline to the saline return channel 18 being blocked. Thus, with the embodiment of Figure 2 when a vapour pocket is created, some saline forming the conduction path between the active electrode 11 and the return electrode 12 can escape due to tissue obstructing the entrance to the return channel 18. This saline can be of a sufficiently high temperature to cause some peripheral tissue blanching. As tissue blanching is dependent upon the size of the instrument, the instrument of Figure 2 should have small dimensions, so that the amount of peripheral blanching can be maintained at acceptable levels. With the embodiment of Figure 3, on the other hand, the return path of saline from the active electrode 11 to the return channel 18 will then never be obstructed by tissue. Moreover, when the conduction path between the active electrode 11 and the return electrode 12 is obstructed, the portion of saline obstructed from the active electrode 11 has a reduced power dissipation. This reduced dissipation arises from the fact that both inlet and output saline are connected to the return channel 18, so the impedance

is lower to the extent that the majority of power dissipation then occurs in the obstructing tissue.

[0058] The instrument of Figure 3 is, therefore, less suitable for miniaturisation than that of Figure 2, due both to the extra tubing (the extra return electrode 12') and the aspect ratio of the tip (i.e. the active electrode 11 cannot protrude as much per diameter due to the saline exhaust being stepped further back). This exhaust has to be positioned further back, as it is passed through the second return electrode 12'. If it were not so positioned, it would cause too great a power distribution over the length of the active electrode 11.

[0059] The exhaust saline from the instrument of Figure 3 may also contain tissue particulates. As the exhaust path does not necessarily pass through a vaporising region, this imposes a limit to the minimum size of this version of the instrument, due to the potential for blockage of the exhaust path.

[0060] The best vaporising performance for each of the instruments described above is when the active electrode 11 is designed to trap, or at least interrupt, saline flow. The reason for this is quite simple, namely that the longer saline can be kept in close proximity to the active electrode 11 the more power it absorbs, and hence the greater the propensity to form a vapour. Wire or hollow forms of active electrode are, therefore, the most effective. It would, for example, be possible to replace the twisted form of wire form of active electrode by an active electrode in the form of a coil. It would also be possible to improve vaporisation by partially obscuring the active electrode/saline interface by masking with sprayed ceramic, sprayed ceramic being deposited at a particulate non-uniform coating.

[0061] The instruments described above have a number of advantages namely:-

1. Each can provide a monopolar like action with only one electrode (the active electrode 11) in direct tissue contact;
2. Each provides immediate tissue debulking (vaporisation) in a manner similar to that obtained with laser instruments;
3. RF current is confined to the area of treatment, thereby reducing collateral or deep thermal effects, and eliminating remote burns;
4. There is minimal smoke when cutting or vaporising, due to the cooling, condensing and dissolving effects of the surrounding saline. Any smoke produced is rapidly removed due to the suction adjacent to the active electrode 11;
5. As the current path within the electrode assembly is bi-directional, there is minimal capacitive coupling at any electrode entry points;

6. The saline provides an excellent active electrode/tissue interface which preserves current flow for a controlled depth of coagulation, this being dependent purely on power and application time.

7. The saline connection prevents high impedance conditions which could cause significant carbonization which is known to be detrimental to tissue healing, and increases the risk of adhesion formation;

8. The excellent low impedance active electrode/tissue interface permits the use of much higher powers for rapid effects. This is particularly useful for quick non-carbonizing coagulation; and

9. Much higher power levels are supported than for conventional bipolar electrosurgery. In practice, conventional bipolar electrosurgery is only effective to a limit of 40W or 50W, as higher power levels result in overheating and carbonization. With the electrode configuration of Figures 2 and 3 power levels in excess of 200W can be supported.

[0062] It will be apparent that modifications could be made to the instruments described above. Thus, the active electrode 11 could be of any other suitable form, such as a needle electrode or a hollow, perforated part-spherical electrode made, for example, of platinum/iridium, and the insulator/spacer 15 would be made of silicone rubber or glass. It would also be possible to replace saline as the conductive medium with a conductive gas such as argon. In this case, the argon would need to be pumped to the region of the active electrode 11 through the channel 17, and there would be no need to remove the argon via the return channel 18, there being no danger of collateral tissue damage from hot argon. In this case also, a modified form of RF generator would be needed. The entire electrode assembly could be constructed as a flexible or rigid assembly, and could also incorporate means for steering or manipulating the active tip, or insertion into tissue.

Claims

1. An electrosurgical instrument for the treatment of tissue in the presence of an electrically-conductive fluid, the instrument comprising an instrument shaft (12) and an electrode assembly at one end of the shaft, the electrode assembly comprising a tissue treatment electrode (11) and a return electrode (12) which is electrically insulated from the tissue treatment electrode by means of an insulation member (15), the tissue treatment electrode being exposed at the extreme distal end of the instrument, and the return electrode having a fluid contact surface spaced from the exposed end of the tissue treatment electrode by the insulation member, wherein

the instrument further comprises feed means (17) for feeding electrically-conductive fluid to the region of the exposed end of the tissue treatment electrode in such a manner as to define, in use, a conductive fluid path that completes an electrical circuit between the tissue treatment electrode and the return electrode, and characterized in that the return electrode is a tubular member which is externally coated in insulation.

2. An electrosurgical instrument as claimed in claim 1, further comprising removal means (18) for removing electrically-conductive fluid from the region of the exposed end of the tissue treatment electrode (11),

3. An electrosurgical instrument as claimed in claim 2, wherein the feed means feeds cool electrically-conductive fluid to the region of the exposed end of the tissue treatment electrode, and the removal means removes heated fluid from said region.

4. An electrosurgical instrument as claimed in claim 2 or claim 3, wherein the removal means is constituted by a fluid return channel (18) formed within the instrument shaft (12), and by means for applying suction to the proximal end of the fluid return channel.

5. An electrosurgical instrument as claimed in any one of claims 1 to 4, wherein the feed means is constituted by a fluid feed channel (17) formed within the instrument shaft (12).

6. An electrosurgical instrument as claimed in claim 5 when appendant to claim 4, wherein the fluid feed channel (17) is positioned around the fluid return channel (18).

7. An electrosurgical instrument as claimed in any one of claims 1 to 6, wherein the return electrode (12) is a tubular member and constitutes the instrument shaft.

8. An electrosurgical instrument as claimed in claim 7, wherein the inner surface of the tubular member (12) constitutes the return electrode.

9. An electrosurgical instrument as claimed in claim 7 or claim 8, wherein the tubular member (12) is made of stainless steel.

10. An electrosurgical instrument as claimed in any one of claims 7 to 9, wherein the tissue treatment electrode (11) is supported centrally within the tubular member (12) by an insulating spacer (15).

11. An electrosurgical instrument as claimed in claim

10, wherein the insulating spacer (15) is made of ceramic material, silicone rubber or glass.

12. An electrosurgical instrument as claimed in claim 10 or claim 11, further comprising a tube (16) extending proximally of the spacer. 5
13. An electrosurgical instrument as claimed in claim 12 when appendant to claim 6, wherein the feed channel (17) is constituted by the annular space between the return electrode (12) and the tube (16), and the return channel (18) is constituted by the interior of the tube and aperture means extending through the spacer (15). 10 15
14. An electrosurgical instrument as claimed in any one of claims 6 to 12, further comprising a second return electrode (12'), the second return electrode being constituted by a second tubular member positioned concentrically within the first-mentioned tubular member (12). 20
15. An electrosurgical instrument as claimed in claim 14 when appendant to claims 6 and 12, wherein the feed channel (17) is constituted by the annular space between the two return electrodes (12, 12') and the return channel (18) is constituted by the annular space between the second return electrode (12'), and the return channel (18) is constituted by the annular space between the second return electrode (12') the tube (16). 25 30
16. Electrosurgical apparatus comprising a radio frequency generator (1) and an electrosurgical instrument for the treatment of tissue in the presence of an electrically-conductive fluid medium, wherein the electrosurgical instrument is as claimed in any one of claims 1 to 15. 35
17. Apparatus as claimed in claim 16, wherein the radio frequency generator (1) includes control means for varying the output power delivered to the electrodes 911, 12, 12'). 40
18. Apparatus as claimed in claim 17 wherein the control means is such as to provide output power in first and second output ranges, the first output range being for powering the electrosurgical instrument for tissue desiccation, and the second output range being for powering the electrosurgical instrument for tissue removal by cutting or vaporisation. 45 50
19. Apparatus as claimed in claim 18, wherein the first output range is from about 150 volts to 200 volts, and the second output range is from about 25 volts to 600 volts, the voltages being peak voltages. 55

Patentansprüche

1. Elektrochirurgisches Instrument zur Behandlung von Gewebe in Gegenwart eines elektrisch leitfähigen Fluids, wobei das Instrument einen Instrumentenschaft (12) und eine Elektrodenanordnung an einem Ende des Schaftes aufweist, wobei die Elektrodenanordnung eine Gewebebehandlungselektrode (11) und eine Rücklaufelektrode (12) besitzt, welche von der Gewebebehandlungselektrode mittels eines Isolierelements (15) elektrisch isoliert ist, wobei die Gewebebehandlungselektrode an dem äußersten distalen Ende des Instruments frei liegt und wobei die Rücklaufelektrode eine Fluidkontaktfläche besitzt, die von dem frei liegenden Ende der Gewebebehandlungselektrode mittels eines Regulierelements beabstandet ist, wobei das Instrument weiterhin eine Zuführeinrichtung (17) zum Zuführen von elektrisch leitfähigem Fluid in den Bereich des frei liegenden Endes der Gewebebehandlungselektrode derart aufweist, dass bei Anwendung ein leitfähiger Fluidweg, der einen elektrischen Kreis zwischen der Gewebebehandlungselektrode und der Rücklaufelektrode vervollständigt, gebildet wird, dadurch gekennzeichnet, dass die Rücklaufelektrode aus einem rohrförmigen Element besteht, das zur Isolierung extern beschichtet ist.
2. Elektrochirurgisches Instrument nach Anspruch 1, weiterhin mit einer Entfernungseinrichtung (18) zum Beseitigen elektrisch leitfähigen Fluids aus dem Bereich des frei liegenden Endes der Gewebebehandlungselektrode (11).
3. Elektrochirurgisches Instrument nach Anspruch 2, bei dem die Zuführeinrichtung kaltes elektrisch leitfähiges Fluid zu dem Bereich des freien Endes der Gewebebehandlungselektrode zuführt und die Entfernungseinrichtung erhitztes Fluid aus dem Bereich abführt.
4. Elektrochirurgisches Instrument nach Anspruch 2 oder 3, bei dem die Entfernungseinrichtung mittels eines Fluidrückführkanals (18), der im Innern des Instrumentenschafts (12) gebildet ist, und durch Saugbeaufschlagung des proximalen Endes des Fluidrücklaufkanals gebildet ist.
5. Elektrochirurgisches Instrument nach einem der Ansprüche 1 bis 4, bei dem die Zuführeinrichtung durch einen Fluidzuführkanal (17) gebildet ist, der im Innern des Instrumentenschafts (12) geformt ist.
6. Elektrochirurgisches Instrument nach Anspruch 5 in Verbindung mit Anspruch 4, bei dem der Fluidzuführkanal (17) um den Fluidrücklaufkanal (18) angeordnet ist.

7. Elektrochirurgisches Instrument nach einem der Ansprüche 1 bis 6, bei dem die Rücklaufelektrode (12) ein rohrförmiges Teil ist und den Instrumentenschaft bildet.
8. Elektrochirurgisches Instrument nach Anspruch 7, bei dem die Innenfläche des rohrförmigen Teils (12) die Rücklaufelektrode bildet.
9. Elektrochirurgisches Instrument nach Anspruch 7 oder 8, bei dem das rohrförmige Teil (12) aus Edelstahl hergestellt ist.
10. Elektrochirurgisches Instrument nach einem der Ansprüche 7 bis 9, bei dem die Gewebebehandlungselektrode (11) mittig innerhalb des rohrförmigen Teils (12) mittels eines isolierenden Abstandsteils gelagert ist.
11. Elektrochirurgisches Instrument nach Anspruch 10, bei dem das isolierende Abstandsteil (15) aus einem keramischen Material aus Silikongummi oder Glas besteht.
12. Elektrochirurgisches Instrument nach Anspruch 10 oder 11, weiterhin mit einem Rohr (16), das sich proximal von dem Abstandsteil erstreckt.
13. Elektrochirurgisches Instrument nach Anspruch 12, in Abhängigkeit von Anspruch 6, bei dem der Zuführkanal (17) durch den ringförmigen Raum zwischen der Rücklaufelektrode (12) und dem Rohr (16) gebildet ist und bei dem der Rückführkanal (18) durch das Innere des Rohres und die Richtung des Abstandsteils (15) erstreckende Öffnungseinrichtung gebildet ist.
14. Elektrochirurgisches Instrument nach einem der Ansprüche 6 bis 12, weiterhin mit einer zweiten Rücklaufelektrode (12'), wobei die zweite Rücklaufelektrode von einem zweiten rohrförmigen Teil gebildet ist, das konzentrisch innerhalb des zuerst erwähnten rohrförmigen Teils (12) angeordnet ist.
15. Elektrochirurgisches Instrument nach Anspruch 14 in Abhängigkeit von den Ansprüchen 6 und 12, bei dem der Zuführkanal (17) durch den ringförmigen Raum zwischen den beiden Rücklaufelektroden (12, 12') gebildet ist und bei dem der Rücklaufkanal (18) durch den ringförmigen Raum zwischen der zweiten Rücklaufelektrode (12') gebildet ist und bei dem der Rücklaufkanal (18) durch den ringförmigen Raum zwischen der zweiten Rücklaufelektrode (12') des Rohrs (16) gebildet ist.
16. Elektrochirurgisches Gerät mit einem Hochfrequenzgenerator (1) und einem elektrochirurgischen Instrument zur Behandlung von Gewebe in Gegen-

wart eines elektrisch leitfähigen Fluidmediums, bei dem das elektrochirurgische Instrument nach einem der Ansprüche 1 bis 15 ausgebildet ist.

17. Gerät nach Anspruch 16, bei dem zu dem Hochfrequenzgenerator (1) eine Steuereinrichtung zur Veränderung der an die Elektroden (11, 12, 12') gelieferten Ausgangsspannung gehört.
18. Gerät nach Anspruch 17, bei dem die Steuereinrichtung derart ausgelegt ist, dass sie in ersten und zweiten Abgabebereichen Ausgangsspannung liefert, wobei der erste Abgabebereich für das Bestromen des elektrochirurgischen Instruments zur Gewebeaustrocknung und der zweite Abgabebereich zur Bestromung des elektrochirurgischen Instruments zur Gewebeentfernung durch Schneiden oder Verdampfung vorgesehen ist.
19. Gerät nach Anspruch 18, bei dem der erste Abgabebereich von etwa 150 Volt bis 200 Volt und der zweite Abgabebereich von etwa 25 Volt bis 600 Volt beträgt, wobei die Spannungen Spitzenspannungen sind.

Revendications

1. Instrument électrochirurgical pour le traitement d'un tissu en présence d'un fluide conducteur, l'instrument comprenant une gaine d'instrument (12) et un assemblage d'électrodes à une extrémité de la gaine, l'assemblage d'électrodes comprenant une électrode de traitement de tissu (11) et une électrode de référence (12) qui est isolée électriquement de l'électrode de traitement de tissu au moyen d'un élément isolant (15), l'électrode de traitement de tissu étant exposée à l'extrémité distale extrême de l'instrument, et la surface de contact avec le fluide de l'électrode de référence étant espacée de l'extrémité exposée de l'électrode de traitement de tissu par l'élément isolant, l'instrument comprenant en outre un système d'alimentation (17) pour amener le fluide conducteur à la région de l'extrémité exposée de l'électrode de traitement de tissu de manière à définir, en service, un passage de fluide conducteur qui complète un circuit électrique entre l'électrode de traitement de tissu et l'électrode de référence, et caractérisé en ce que l'électrode de référence est un élément tubulaire qui est muni d'un revêtement isolant externe.
2. Instrument électrochirurgical selon la revendication 1, comprenant en outre un système d'extraction (18) pour extraire le fluide conducteur de la région de l'extrémité exposée de l'électrode de traitement de tissu (11).

3. Instrument électrochirurgical selon la revendication 2, dans lequel le système d'alimentation amène un fluide conducteur frais à la région de l'extrémité exposée de l'électrode de traitement de tissu, et le système d'extraction extrait du fluide chauffé de ladite région.
4. Instrument électrochirurgical selon la revendication 2 ou 3, dans lequel le système d'extraction est constitué par un canal de retour du fluide (18) formé dans la gaine d'instrument (12) et par un système destiné à appliquer une aspiration à l'extrémité proximale du canal de retour du fluide.
5. Instrument électrochirurgical selon l'une quelconque des revendications 1 à 4, dans lequel le système d'alimentation est constitué par un canal d'amenée du fluide (17) formé dans la gaine d'instrument (12).
6. Instrument électrochirurgical selon la revendication 5 dépendante de la revendication 4, dans lequel le canal d'amenée du fluide (17) est disposé autour du canal de retour du fluide (18).
7. Instrument électrochirurgical selon l'une quelconque des revendications 1 à 6, dans lequel l'électrode de référence (12) est un élément tubulaire et constitue la gaine de l'instrument.
8. Instrument électrochirurgical selon la revendication 7, dans lequel la surface interne de l'élément tubulaire (12) constitue l'électrode de référence.
9. Instrument électrochirurgical selon la revendication 7 ou la revendication 8, dans lequel l'élément tubulaire (12) est en acier inoxydable.
10. Instrument électrochirurgical selon l'une quelconque des revendications 7 à 9, dans lequel l'électrode de traitement de tissu (11) est soutenue en position centrale dans l'élément tubulaire (12) par une entretoise isolante (15).
11. Instrument électrochirurgical selon la revendication 10, dans lequel l'entretoise isolante (15) est constituée d'un matériau céramique, de caoutchouc silicone ou de verre.
12. Instrument électrochirurgical selon la revendication 10 ou la revendication 11, comprenant en outre un tube (16) s'étendant dans la région proximale de l'entretoise.
13. Instrument électrochirurgical selon la revendication 12 dépendante de la revendication 6, dans lequel le canal d'alimentation (17) est constitué par l'espace annulaire compris entre l'électrode de référence (12) et le tube (16), et le canal de retour (18) est constitué par l'intérieur du tube et le système d'ouverture à travers l'espaceur (15).
14. Instrument électrochirurgical selon l'une quelconque des revendications 6 à 12, comprenant en outre une seconde électrode de référence (12'), le seconde électrode de référence étant constituée par un second élément tubulaire disposé en position concentrique dans le premier élément tubulaire (12).
15. Instrument électrochirurgical selon la revendication 14 dépendante des revendications 6 à 12, dans lequel le canal d'alimentation (17) est constitué par l'espace annulaire compris entre les deux électrodes de référence (12, 12') et le canal de retour (18) est constitué par l'espace annulaire compris entre la seconde électrode de référence (12') et le tube (16).
16. Appareil électrochirurgical comprenant un générateur de fréquence radio (1) et un instrument électrochirurgical pour le traitement d'un tissu en présence d'un milieu fluide conducteur, dans lequel l'instrument électrochirurgical est tel que revendiqué dans l'une quelconque des revendications 1 à 15.
17. Appareil selon la revendication 16, dans lequel le générateur de fréquence radio (1) comprend un système de commande pour la variation de la puissance de sortie délivrée aux électrodes (11, 12, 12').
18. Appareil selon la revendication 17, dans lequel le système de commande permet de fournir une puissance de sortie dans un premier et un second intervalle de sortie, le premier intervalle de sortie devant alimenter l'instrument électrochirurgical pour la dessiccation du tissu et le second intervalle de sortie devant alimenter l'instrument électrochirurgical pour l'enlèvement du tissu par section ou vaporisation.
19. Appareil selon la revendication 18, dans lequel le premier intervalle de sortie est compris entre environ 150 volts et 200 volts, et le second intervalle de sortie est compris entre environ 25 volts et 600 volts, les tensions étant des tensions de crête.
